

Marsapiens + EventForge: Discussion Brief

Marsapiens started as a science-fiction civilization simulation where humanity establishes colonies on Mars. A broader opportunity emerged: create a reusable planetary analytics platform that powers Marsapiens and future simulations. The working name is EventForge. EventForge acts as a telemetry and observability platform capable of processing massive event streams generated by civilizations, infrastructure, economies, AI agents, and environmental systems.

Vision and Core Idea

The platform combines real-world and synthetic data. Real sources may include weather, NASA datasets, commodity prices, planetary data, and space weather. Synthetic sources include population growth, agriculture, energy grids, mining, research, transportation, and governance. Instead of monitoring servers, the platform monitors entire civilizations and planets. Marsapiens becomes the first application built on top of the platform.

Architecture and Roadmap

Architecture: Data Generators → Kafka → Stream Processing → ClickHouse → Analytics API → Dashboards. Phase 1 focuses on 100M events/day and Mars colony telemetry. Phase 2 introduces a Mars Digital Twin. Phase 3 expands to Earth and hybrid real/synthetic data. Phase 4 evolves into a Solar System Civilization Simulator. Key discussion point: should this be a game backend with analytics attached, or a generic analytics platform where the game is one consumer? Current preference is the second option due to scalability, reuse, and stronger technical differentiation.
